Dmytriw, MD; Timo Krings, MD; Colin P. Derdeyn, MD; Liqun Jiao, MD; for the CASSISS Trial Investigators

Background Prior randomized trials have generally shown harm or no benefit of stenting added to medical therapy for patients with symptomatic severe intracranial atherosclerotic stenosis, but it remains uncertain as to whether refined patient selection and more experienced surgeons might result in improved outcomes.

Objective To compare stenting plus medical therapy vs medical therapy alone in patients with symptomatic severe intracranial atherosclerotic stenosis.

Design, Setting, and Participants Multicenter, open-label, randomized, outcome assessor-blinded trial conducted at 8 centers in China. A total of 380 patients with transient ischemic attack or nondisabling, nonperforator (defined as nonbrainstem or non-basal ganglia end artery) territory ischemic stroke attributed to severe intracranial stenosis (70%-99%) and beyond a duration of 3 weeks from the latest ischemic symptom onset were recruited between March 5, 2014, and November 10, 2016, and followed up for 3 years (final follow-up: November 10, 2019).

Interventions Medical therapy plus stenting (n = 176) or medical therapy alone (n = 182). Medical therapy included dual-antiplatelet therapy for 90 days (single antiplatelet therapy thereafter) and stroke risk factor control.

Main Results and Conclusions The primary outcome was a composite of stroke or death within 30 days or stroke in the qualifying artery territory beyond 30 days through 1 year. There were 5 secondary outcomes, including stroke in the qualifying artery territory at 2 years and 3 years as well as mortality at 3 years.

Conclusions Among 380 patients who were randomized, 358 were confirmed eligible (mean age, 56.3 years; 263 male [73.5%]) and 343 (95.8%) completed the trial. For the stenting plus medical therapy group vs medical therapy alone, no significant difference was found for the primary outcome of risk of stroke or death (8.0% [14/176] vs 7.2% [13/181]; difference, 0.4% [95% CI, -5.0% to 5.9%]; hazard ratio, 1.10 [95% CI, 0.52-2.35]; $P = .82$). Of the 5 prespecified secondary end points, none showed a significant difference including stroke in the qualifying artery territory at 2 years (9.9% [17/171] vs 9.0% [16/178]; difference, 0.7% [95% CI, -5.4% to 6.7%]; hazard ratio, 1.10 [95% CI, 0.56-2.16]; $P = .80$) and 3 years (11.3% [19/168] vs 11.2% [19/170]; difference, -0.2% [95% CI, -7.0% to 6.5%]; hazard ratio, 1.00 [95% CI, 0.53-1.90]; $P > .99$). Mortality at 3 years was 4.4% (7/160) in the stenting plus medical therapy group vs 1.3% (2/159) in the medical therapy alone group (difference, 3.2% [95% CI, -0.5% to 6.9%]; hazard ratio, 3.75 [95% CI, 0.77-18.13]; $P = .08$).

Conclusions Among patients with transient ischemic attack or ischemic stroke due to symptomatic severe intracranial atherosclerotic stenosis, the addition of percutaneous transluminal angioplasty and stenting to medical therapy, compared with medical therapy alone, resulted in no significant difference in the risk of stroke or death within 30 days or stroke in the qualifying artery territory beyond 30 days through 1 year. The findings do not support the addition of percutaneous transluminal angioplasty and stenting to medical therapy for the treatment of patients with symptomatic severe intracranial atherosclerotic stenosis.

Characteristic	No. (%) Percutaneous transluminal angioplasty and stenting group (n = 176)	Medical therapy alone group (n = 182)
NIHSS score, median (IQR) ^f	0.0 (0.0-1.0)	0.0 (0.0-0.0)
mRS score, median (IQR) ^g	0.0 (0.0-1.0)	0.0 (0.0-1.0)

Abbreviations: mRS, modified Rankin Scale; NIHSS, National Institutes of Health Stroke Scale; TIA, transient ischemic attack.

^a Ethnicity was self-reported.

^b Medical history was collected at the baseline visit, based on a combination of self-reports from patients, medicated conditions, and laboratory results.

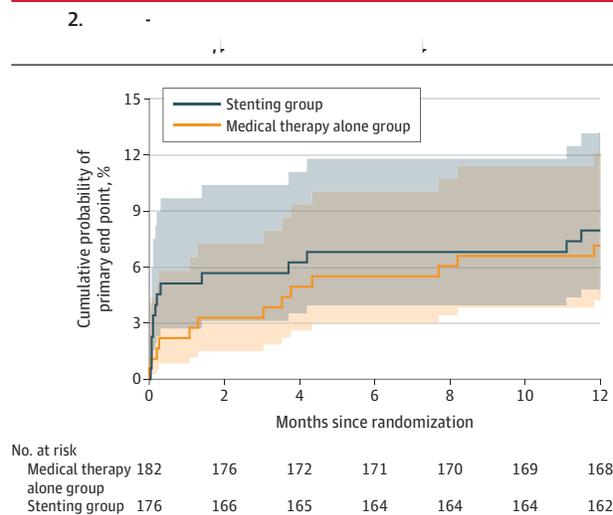

^c TIA was a clinical diagnosis without imaging.

^d Isolated hemodynamic compromise refers to strokes with an arterial border zone or "watershed" pattern.

^e Stenosis was quantified on the basis of a reading of the angiogram by the site interventionalist on the criteria of the WASID trial.¹⁸

^f NIHSS score ranges from 0 to 42, with higher scores indicating worse neurologic deficits.

^g mRS score ranges from 0 to 6, with higher scores indicating worse function deficits (0 indicates no deficit and 6 indicates death).

The primary outcome was stroke or death within 30 days after enrollment or stroke in the qualifying artery territory beyond 30 days through 1 year. One patient lost to follow-up within 1 year in the control group was treated as censored data. All other patients were followed up to event or 1 year. $P = .82$ for log-rank testing between the stenting and medical therapy alone groups with center as stratification factor.

$P = .82$ (Figure 2 a, Table 2). The cumulative probability of the primary outcome was significantly higher in the stenting group compared with the medical therapy alone group (HR, 1.12; 95% CI, 1.01-1.24; $P = .03$) (Forest plot, Supplemental Figure 1).

None of the secondary outcomes were significantly different between the stenting and medical therapy alone groups. The cumulative probability of death was significantly higher in the stenting group compared with the medical therapy alone group (HR, 1.12; 95% CI, 1.01-1.24; $P = .03$). The cumulative probability of stroke was significantly higher in the stenting group compared with the medical therapy alone group (HR, 1.12; 95% CI, 1.01-1.24; $P = .03$). The cumulative probability of death or stroke was significantly higher in the stenting group compared with the medical therapy alone group (HR, 1.12; 95% CI, 1.01-1.24; $P = .03$).

^b Adjusted for site effect.

^c Log-rank test adjusted for site effect.

^d Post hoc analysis.

^e There were 5 ischemic stroke and 4 hemorrhagic strokes. Of the 4 symptomatic hemorrhagic strokes, 1 was periprocedural subarachnoid hemorrhage immediately after percutaneous transluminal angioplasty and stenting (probably related to guidewire perforation); 1 was periprocedural parenchymal and subdural brain hemorrhage evident immediately after percutaneous transluminal angioplasty and stenting (probably related to guidewire perforation); 1 was cerebellar and occipital hemorrhage that occurred 3 days after percutaneous transluminal angioplasty and stenting (probably related to reperfusion); and 1 was subarachnoid hemorrhage within 24 hours after percutaneous transluminal angioplasty and stenting (probably related to reperfusion). A total of 2 of these hemorrhages were fatal (1 developed massive cerebral infarction and brain hernia, and 1 had parenchymal brain hemorrhage), and 2 were nondisabling (1 cerebellar and occipital hemorrhage and 1 subarachnoid hemorrhage).

^f There were 4 ischemic strokes and 0 hemorrhagic strokes. Of the 4 ischemic strokes, 2 were disabling, 2 were nondisabling, and none were fatal.

^g One missing follow-up and 4 died.

^h Four missing follow-up and 0 died.

ⁱ Four missing follow-up and 4 died.

^j Eleven missing follow-up and 1 died.

^k Eight missing follow-up, including 4 with primary outcomes (but no disabling stroke or death).

^l Sixteen missing follow-up, including 5 with primary outcomes (but no disabling stroke or death).

^m Four missing follow-up and 3 died.

ⁿ Ten missing follow-up and 0 died.

^o Sixteen missing follow-up, including 12 with primary outcomes.

^p The causes of death in the percutaneous transluminal angioplasty and stenting group were as follows: brain hemorrhage (n = 2), ischemic stroke (n = 2), sudden cardiac arrest (n = 1), intrahepatic cholangiocarcinoma (n = 1), and aortic artery aneurysm (n = 1).

^q Twenty-three missing follow-up, including 12 with primary outcomes.

^r The causes of death in the medical management group were as follows: ischemic stroke (n = 1) and brain hemorrhage (n = 1).

stroke, 2 were disabling, 2 were nondisabling, and none were fatal. (Figure 1). The hazard ratio (95% CI) for stroke or death within 30 days after enrollment was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the territory of the qualifying artery beyond 30 days through 1 year was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the same territory within 2 years was 1.10 (95% CI, 0.56 to 2.16) (P = .80). The hazard ratio (95% CI) for stroke in the same territory within 3 years was 1.00 (95% CI, 0.53 to 1.90) (P > .99). The hazard ratio (95% CI) for disabling stroke or death within 3 years was 1.28 (95% CI, 0.65 to 2.52) (P = .49). The hazard ratio (95% CI) for any stroke, TIA, cardiovascular events related to stenting or medical therapy within 3 years was 0.76 (95% CI, 0.45 to 1.30) (P = .31). The hazard ratio (95% CI) for death within 3 years was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for stroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for nonstroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08).

hazard ratio (95% CI) for stroke or death within 30 days after enrollment was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the territory of the qualifying artery beyond 30 days through 1 year was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the same territory within 2 years was 1.10 (95% CI, 0.56 to 2.16) (P = .80). The hazard ratio (95% CI) for stroke in the same territory within 3 years was 1.00 (95% CI, 0.53 to 1.90) (P > .99). The hazard ratio (95% CI) for disabling stroke or death within 3 years was 1.28 (95% CI, 0.65 to 2.52) (P = .49). The hazard ratio (95% CI) for any stroke, TIA, cardiovascular events related to stenting or medical therapy within 3 years was 0.76 (95% CI, 0.45 to 1.30) (P = .31). The hazard ratio (95% CI) for death within 3 years was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for stroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for nonstroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08).

A hazard ratio (95% CI) for stroke or death within 30 days after enrollment was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the territory of the qualifying artery beyond 30 days through 1 year was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the same territory within 2 years was 1.10 (95% CI, 0.56 to 2.16) (P = .80). The hazard ratio (95% CI) for stroke in the same territory within 3 years was 1.00 (95% CI, 0.53 to 1.90) (P > .99). The hazard ratio (95% CI) for disabling stroke or death within 3 years was 1.28 (95% CI, 0.65 to 2.52) (P = .49). The hazard ratio (95% CI) for death within 3 years was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for stroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for nonstroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08).

I hazard ratio (95% CI) for stroke or death within 30 days after enrollment was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the territory of the qualifying artery beyond 30 days through 1 year was 1.10 (95% CI, 0.52 to 2.35) (P = .82). The hazard ratio (95% CI) for stroke in the same territory within 2 years was 1.10 (95% CI, 0.56 to 2.16) (P = .80). The hazard ratio (95% CI) for stroke in the same territory within 3 years was 1.00 (95% CI, 0.53 to 1.90) (P > .99). The hazard ratio (95% CI) for disabling stroke or death within 3 years was 1.28 (95% CI, 0.65 to 2.52) (P = .49). The hazard ratio (95% CI) for any stroke, TIA, cardiovascular events related to stenting or medical therapy within 3 years was 0.76 (95% CI, 0.45 to 1.30) (P = .31). The hazard ratio (95% CI) for death within 3 years was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for stroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08). The hazard ratio (95% CI) for nonstroke-related death was 3.75 (95% CI, 0.77 to 18.13) (P = .08).

Abstract

Background: Intracranial stenosis (ICS) is a common cause of stroke. The effect of stenting plus medical therapy (STMT) vs medical therapy alone (MTA) on the risk of stroke and death in ICS remains unclear.

Objective: To compare the effect of STMT vs MTA on the risk of stroke and death in ICS.

Design: A retrospective cohort study.

Setting: A tertiary care hospital.

Participants: Patients with ICS who were treated with STMT or MTA.

Measurements and Main Results: The primary outcome was the risk of stroke and death. The secondary outcome was the risk of stroke and death without major adverse neurological events (MACE). The STMT group had a significantly lower risk of stroke and death compared with the MTA group (hazard ratio [HR], 0.58; 95% confidence interval [CI], 0.38-0.88; *P* = .008). The STMT group also had a significantly lower risk of stroke and death without MACE compared with the MTA group (HR, 0.58; 95% CI, 0.38-0.88; *P* = .008).

Conclusions: STMT significantly reduced the risk of stroke and death compared with MTA in patients with ICS.

Introduction

Intracranial stenosis (ICS) is a common cause of stroke, and it is associated with a high risk of stroke and death. The effect of stenting plus medical therapy (STMT) vs medical therapy alone (MTA) on the risk of stroke and death in ICS remains unclear. The STMT group had a significantly lower risk of stroke and death compared with the MTA group (hazard ratio [HR], 0.58; 95% confidence interval [CI], 0.38-0.88; *P* = .008). The STMT group also had a significantly lower risk of stroke and death without major adverse neurological events (MACE) compared with the MTA group (HR, 0.58; 95% CI, 0.38-0.88; *P* = .008).

Conclusions

A retrospective cohort study comparing the effect of stenting plus medical therapy (STMT) vs medical therapy alone (MTA) on the risk of stroke and death in patients with intracranial stenosis (ICS). The STMT group had a significantly lower risk of stroke and death compared with the MTA group (hazard ratio [HR], 0.58; 95% confidence interval [CI], 0.38-0.88; *P* = .008). The STMT group also had a significantly lower risk of stroke and death without major adverse neurological events (MACE) compared with the MTA group (HR, 0.58; 95% CI, 0.38-0.88; *P* = .008).
